1 Introduction

StumpWM is an X11 window manager written entirely in Common Lisp. Its user interface goals are similar to ratpoison’s but with an emphasis on customizability, completeness, and cushiness.

1.1 Starting StumpWM

There are a number of ways to start StumpWM but the most straight forward method is as follows. This assumes you have a copy of the StumpWM source code and are using the ‘SBCL’ Common Lisp environment.

1. Install sbcl, the portable-clx package, and cl-ppcre. In Debian, portable-clx is the cl-clx-sbcl package. You can also use asdf-install to download and install clx:

   $ sbcl
   * (require :asdf)
   * (require :asdf-install)
   * (asdf-install:install :clx)
   * (asdf-install:install :cl-pcre)

   Note that asdf-install requires gnupg.

2. In the stumpwm directory, run ./configure.

3. run make. If all goes well, this should create a stumpwm executable.

4. In your ~/.xinitrc file include the line /path/to/stumpwm. Remember to replace ‘/path/to/’ with the actual path.

5. Finally, start X windows with startx. Cross your fingers. You should see a ‘Welcome To the Stump Window Manager’ message pop up in the upper, right corner. At this point, you have successfully started StumpWM.

1.2 Basic Usage

Once you have StumpWM up and running, the first thing you might want to do is start emacs. Type C-t e, or in other words Control + t followed by e. Now perhaps you want an xterm. Type C-t c. Now you have some programs running.

To see a list of windows StumpWM is managing, type C-t w. The highlighted window is the one you’re looking at right now. It’s the focused window.

All of StumpWM’s keys are bound to named commands, which can be executed not only by keys but also from the input bar. Type C-t ; to open a command prompt. Now type time and press return. Note, time can also be called by typing C-t a. Throughout this manual you’ll find definitions for commands, functions, and variables. Any command you see in this manual can be executed from the input bar or bound to a key.

At this point you probably want to switch back from your new xterm to emacs. Type C-t C-t. This runs the other command. Type it again and you’re back to xterm.

Perhaps you’d like to see emacs and xterm side-by-side. Type C-t s. You have now split the screen into 2 frames. For more information see Chapter 6 [Frames], page 21. To switch to the empty frame type C-t TAB. Now let’s pull the xterm window into this empty frame. Type C-t w for a window listing. Find the xterm window. See the number beside it? Type C-t followed by xterm’s window number.
Another common activity is browsing the interwebs. Type C-t !. The input bar pops up again. You can now run a shell command. Let’s start a web browser: type `firefox` into the input bar and press return.

Unfortunately, `firefox` probably isn’t wide enough because it’s in one of the frames. Type C-t Q to remove all frames but the current one and resize it to fit the screen.

For a full list of key bindings, see Section 2.1 [List of Default Keybindings], page 3.

1.3 Interacting with the Lisp process

Since StumpWM is a Lisp program, there is a way for you to evaluate Lisp code directly, on the same Lisp process that StumpWM is running on. Type C-t : and an input box will appear. Then type some Lisp expression.

When you call `eval` this way, you will be in the STUMPWM-USER package, which imports all the exported symbols from the main STUMPWM package.

*mode-line-border-width*
   Reads the value of *mode-line-border-width*.

(setf *mode-line-border-width* 3)
   Sets the variable *mode-line-border-width* to 3.

(set-prefix-key (kbd "C-M-H-s-z"))
   Calls the `set-prefix-key` function (and sets a new keyboard prefix)

1.4 Contact the StumpWM developers

The StumpWM home page is [http://stumpwm.nongnu.org/](http://stumpwm.nongnu.org/).

You can reach Shawn Betts at sabetts at vcn.bc.ca.

The StumpWM mailing list is stumpwm-devel@nongnu.org which you can subscribe to at [http://mail.nongnu.org/mailman/listinfo/stumpwm-devel](http://mail.nongnu.org/mailman/listinfo/stumpwm-devel). Posting is restricted to subscribers to keep spam out of the archives.

The StumpWM IRC channel can be found on Freenode at #stumpwm.
Chapter 2: Key Bindings

2 Key Bindings

StumpWM is controlled entirely by keystrokes and Lisp commands. It mimics GNU Screen's keyboard handling. StumpWM's default prefix key is \texttt{C-t}.

2.1 List of Default Keybindings

The following is a list of keybindings.

\begin{align*}
\text{C-t} & \text{ } d \quad \text{Select the window with the corresponding digit } d \\
\text{C-t} & \text{ } C-d \quad \text{Pull the window with the corresponding digit } d \text{ into the current frame} \\
\text{C-t} & \text{ } n \quad \text{C-t} \ C-n \\
\text{C-t} & \text{ } \text{Space} \quad \text{Go to the next window in the window list} \\
\text{C-t} & \text{ } p \quad \text{C-t} \ C-p \\
\text{C-t} & \text{ } \textquotesingle \quad \text{Go to a window by name} \\
\text{C-t} & \text{ } \textquoteright \quad \text{Select a window from a list and focus the window.} \\
\text{C-t} & \text{ } C-g \quad \text{Abort the current command. This is useful if you accidentally hit } \text{C-t} \\
\text{C-t} & \text{ } w \quad \text{C-t} \ C-w \\
\text{C-t} & \text{ } \text{Space} \quad \text{List all the windows} \\
\text{C-t} & \text{ } i \quad \text{C-t} \ C-i \\
\text{C-t} & \text{ } f \quad \text{C-t} \ C-f \\
\text{C-t} & \text{ } s \quad \text{C-t} \ C-s \\
\text{C-t} & \text{ } S \quad \text{C-t} \ C-S \\
\text{C-t} & \text{ } k \quad \text{C-t} \ C-k \\
\text{C-t} & \text{ } C-k \quad \text{Sends a kill message to the current frame and the running program.} \\
\text{C-t} & \text{ } K \quad \text{Kills the current frame and running program; like } \texttt{kill -9}. \\
\text{C-t} & \text{ } c \quad \text{C-t} \ C-c \\
\text{C-t} & \text{ } C-c \quad \text{Run an X terminal; by default } \texttt{xterm} \\
\text{C-t} & \text{ } e \quad \text{C-t} \ C-e \\
\text{C-t} & \text{ } t \quad \text{C-t} \ C-t \\
\text{C-t} & \text{ } w \quad \text{C-t} \ C-w \quad \text{Prints out a list of the windows, their number, and their name.} \\
\text{C-t} & \text{ } b \quad \text{C-t} \ C-b \quad \text{Banish the mouse point to the lower right corner of the screen.} \\
\text{C-t} & \text{ } a \quad \text{C-t} \ C-a \quad \text{Display the current time and date, much like the Unix command } \texttt{date}. \\
\end{align*}
C-t C-t  Switch to the last window to have focus in the current frame.
C-t !    Prompt for a shell command to run via `/bin/sh`. All output is discarded.
C-t R    If the screen is split into multiple frames, one split will be undone. If there is
         only one split, the effect will be the same as C-t Q.
C-t o    If the screen is split into multiple frames, focus shifts to the next frame, where
         it cycles to the right and then down; analogous to C-x o in Emacs.
C-t TAB   Display “Current Frame” in the frame which has focus.
C-t ;     Opens the input box. StumpWM commands can be run from here, and the
         input history moved through.
C-t :     Opens the input box, but all things typed in here will be sent to the Common
         Lisp interpreter where they will be ran as Lisp programs; thus, input should be
         valid Common Lisp.
C-t C-h   The help.
C-t ?     Hide all frames and show the root window.
C-t Q     Removes all splits and maximizes the frame with focus.
C-t Up    Shift focus to an adjacent frame in the specified direction. C-t Up will shift
         focus up, if possible, C-t Down will shift downwards, etc.
C-t Down
C-t Right
C-t Left
C-t Right  Shift focus to an adjacent frame in the specified direction. C-t Up will shift
focus up, if possible, C-t Down will shift downwards, etc.
C-t v     Prints out the version of the running StumpWM.
C-t #     Toggle the mark on the current window
C-t m
C-t C-m   Display the last message. Hitting this keybinding again displays the message
         before that, and so on.
C-t l
C-t C-l   redisplay the current window and force it to take up the entire frame.
C-t G     Display all groups and windows in each group. For more information see
         Chapter 8 [Groups], page 27.
C-t F n   Jump to the corresponding group n. C-t F1 jumps to group 1 and so on.
C-t g g   Show the list of groups.
C-t g c   Create a new group.
C-t g n
C-t g C-n
C-t g SPC
C-t g C-SPC  Go to the next group in the list.
Chapter 2: Key Bindings

C-t g N  Go to the next group in the list and bring the current window along.
C-t g p  Go to the previous group in the list.
C-t g C-p Go to the previous group in the list and bring the current window along.
C-t g '  Select a group by name or by number.
C-t g "  Select a group from a list and switch to it.
C-t g m  Move the current window to the specified group.
C-t g k  Kill the current group. All windows are merged into the next group.
C-t g A  Change the current group’s name.
C-t g r  Go to the group with digit \textit{d}. C-t g 1 jumps to group 1 and so on.
C-t +  Make frames the same height or width in the current frame’s subtree.
C-t h k  Describe the specified key binding.
C-t h f  Describe the specified function.
C-t h v  Describe the specified variable.
C-t h w  List all key sequences that are bound to the specified command
C-t h c  Describe the specified command.

2.2 Binding Keys

\texttt{define-key map key command} \quad \text{[Function]}
Add a keybinding mapping for the key, \textit{key}, to the command, \textit{command}, in the
specified keymap. If \textit{command} is nil, remove an existing binding. For example,

\begin{verbatim}
(stumpwm:define-key stumpwm:*root-map* (stumpwm:kbd "C-z") "echo Zzzzz...")
\end{verbatim}
Now when you type C-t C-z, you’ll see the text “Zzzzz...” pop up.

\texttt{undefine-key map key} \quad \text{[Function]}
Clear the key binding in the specified keybinding.

\texttt{kdb keys} \quad \text{[Function]}
This compiles a key string into a key structure used by ‘define-key’, ‘undefine-key’,
‘set-prefix-key’ and others.

\texttt{set-prefix-key key} \quad \text{[Command]}
Change the stumpwm prefix key to KEY.

\begin{verbatim}
(stumpwm:set-prefix-key (stumpwm:kdb "C-M-H-s-z"))
\end{verbatim}
This will change the prefix key to Control + Meta + Hyper + Super + the \textit{z} key. By
most standards, a terrible prefix key but it makes a great example.
make-sparse-keymap

Create an empty keymap. If you want to create a new list of bindings in the key binding tree, this is where you start. To hang frame related bindings off C-t C-f one might use the following code:

```lisp
(defvar *my-frame-bindings*
  (let ((m (stumpwm:make-sparse-keymap)))
    (stumpwm:define-key m (stumpwm:kbd "f") "curframe")
    (stumpwm:define-key m (stumpwm:kbd "M-b") "move-focus left")
    m ; NOTE: this is important)
)

(stumpwm:define-key stumpwm:*root-map* (stumpwm:kbd "C-f") '*my-frame-bindings*)
```

*root-map*

This is the keymap by default bound to C-t. It is known as the prefix map.

*top-map*

The top level key map. This is where you'll find the binding for the prefix map.

*groups-map*

The keymap that group related key bindings sit on. It is bound to C-t g by default.

bind key command

Hang a key binding off the escape key.

2.3 Modifiers

Many users have had some difficulty with setting up modifiers for StumpWM keybindings. This is caused by a combination of how StumpWM handles modifiers and the default modifiers list for many users’ X servers.

- My “Super” key doesn’t work!

  This is most likely caused by having the Hyper and Super keys listed as the same modifier in the modifier list.

  $ xmodmap
  xmodmap: up to 3 keys per modifier, (keycodes in parentheses):

<table>
<thead>
<tr>
<th>Shift</th>
<th>Lock</th>
<th>Control</th>
<th>Mod1</th>
<th>Mod2</th>
<th>Mod3</th>
<th>Mod4</th>
<th>Mod5</th>
</tr>
</thead>
</table>
  | Shift_L (0x32), Shift_R (0x3e) | Caps_Lock (0x42) | Control_L (0x25), Control_R (0x6d) | Alt_L (0x25), Alt_R (0x71), Meta_L (0x9c) | Num_Lock (0x4d) | | Super_L (0x7f), Hyper_L (0x80) | Mode_switch (0x5d), ISO_Level3_Shift (0x7c)

The problem is in the line beginning with “mod4”. The way to set up the modifier list correctly is to have just the Super key as the mod4 modifier. The following xmodmap commands will do just that.
# clear out the mod4 modifier
$ xmodmap -e 'clear mod4'
$ xmodmap

xmodmap: up to 3 keys per modifier, (keycodes in parentheses):

shift Shift_L (0x32), Shift_R (0x3e)
lock Caps_Lock (0x42)
control Control_L (0x25), Control_R (0x6d)
mod1 Alt_L (0x40), Alt_R (0x71), Meta_L (0x9c)
mod2 Num_Lock (0x4d)
mod3
mod4 Super_L (0x73), Super_L (0x7f)
mod5 Mode_switch (0x5d), ISO_Level3_Shift (0x7c)

# add Super as a mod4 modifier
$ xmodmap -e 'add mod4 = Super_L'
$ xmodmap

xmodmap: up to 3 keys per modifier, (keycodes in parentheses):

shift Shift_L (0x32), Shift_R (0x3e)
lock Caps_Lock (0x42)
control Control_L (0x25), Control_R (0x6d)
mod1 Alt_L (0x40), Alt_R (0x71), Meta_L (0x9c)
mod2 Num_Lock (0x4d)
mod3
mod4 Super_L (0x73), Super_L (0x7f)
mod5 Mode_switch (0x5d), ISO_Level3_Shift (0x7c)

You can automate this by storing the commands in a file and calling xmodmap when you start your X session.

$ cat ~/.Xmodmap
clear mod4
add mod4 = Super_L

If you use startx, modify your ~/.xsession or ~/.xinitrc file.

$ cat ~/.xsession
#!/bin/sh

xmodmap ~/.Xmodmap
exec /usr/bin/stumpwm

If you use a graphical login manager (GDM, KDM, etc.), your ~/.Xmodmap file should be fed to xmodmap when you log in. FIXME: verify this.

• Handling Meta and Alt: when do I use M- and A-?

If you have no Meta keys defined (see the output of the xmodmap command), then StumpWM will treat the M- prefix in keybindings to mean Alt. However, if there are Meta keys defined, then the M- prefix refers to them, and the A- prefix refers to Alt.
Most users will simply use M- to refer to their Alt keys. However, users that define separate Meta and Alt keys will use M- to refer to the former, and A- to refer to the latter.

- How can I set up a Hyper key and use it with StumpWM?

To set up a Hyper key, you need to do two things: bind a physical key to be a Hyper key, and add that key to the modifiers list.

The following example shows how to bind the control key at the bottom-left of most keyboards to be Hyper. This is useful if you've made Caps Lock into a control key, and have no use for the bottom-left key.

```
$ xmodmap -e 'keycode 37 = Hyper_L'
$ xmodmap -e 'clear mod5'
$ xmodmap -e 'add mod5 = Hyper_L'
```

To use a different key for Hyper, replace the keycode “37” above. Use the xev program to see the keycode that any physical key has. Refer to the section above on setting up the Super key to see how to automate setting the Hyper key when you start X.

Now you can use H- as a prefix in StumpWM bindings.

```
(define-key *top-map* (kbd "H-RET") "fullscreen")
(define-key *top-map* (kbd "H-Left") "gprev")
(define-key *top-map* (kbd "H-Right") "gnext")
(define-key *top-map* (kbd "H-TAB") "other")
```

Since essentially no programs have Hyper bindings, you can safely bind commands to the *top-map*. 
3 Commands

If you’ve used emacs before you’ll find commands and functions familiar. Commands are functions that can be bound to keys and executed interactively from StumpWM’s input bar. A command expects a certain number of arguments and any that are not supplied will be prompted for.

FIXME: actually write some docs here
4 Message and Input Bar

**echo string**  
[Command]  
Display string in the message bar.

**colon &optional initial-input**  
[Command]  
Read a command from the user. initial-text is optional. When supplied, the text will appear in the prompt.

4.1 Customizing The Bar

The bar’s appearance and behavior can be modified with the following functions and variables.

**set-fg-color color**  
[Function]  
Set the foreground color for the message bar and input bar. color can be any color recognized by X.

**set-bg-color color**  
[Function]  
Set the background color for the message bar and input bar. color can be any color recognized by X.

**set-border-color color**  
[Function]  
Set the border color for the message bar and input bar. color can be any color recognized by X.

**set-msg-border-width width**  
[Function]  
Set the border width for the message bar and input bar.

**set-font font**  
[Function]  
Set the font for the message bar and input bar.

***message-window-padding***  
[Variable]  
The number of pixels that pad the text in the message window.

***message-window-gravity***  
[Variable]  
This variable controls where the message window appears. The follow are valid values.

:top-left
:top-right
:bottom-left
:bottom-right
:center

***timeout-wait***  
[Variable]  
Specifies, in seconds, how long a message will appear for. This must be an integer.

***input-window-gravity***  
[Variable]  
This variable controls where the input window appears. The follow are valid values.
4.2 Using The Input Bar

The following is a list of keybindings for the Input Bar. Users of Emacs will recognize them.

- **DEL**: Delete the character before point (delete-backward-char).
- **M-DEL**: Kill back to the beginning of the previous word (backward-kill-word).
- **C-d**: Delete the character after point (delete-forward-char).
- **M-d**: Kill forward to the end of the next word (forward-kill-word).
- **C-f**: Move forward one character (forward-char).
- **M-f**: Move forward one word (forward-word).
- **C-b**: Move backward one character (backward-char).
- **M-b**: Move backward one word (backward-word).
- **C-a**: Move to the beginning of the current line (move-beginning-of-line).
- **C-e**: Move to the end of the current line (move-end-of-line).
- **C-k**: Kill to the end of the line (kill-line).
- **C-u**: Kill to the beginning of the line (kill-to-beginning), the same as C-a C-k.
- **C-p**: Move to the next earlier entry saved in the command history (history-back).
- **C-n**: Move to the next later entry saved in the command history (history-forward).
- **RET**: Submit the entered command (submit).
- **C-g**: Abort the current action by closing the Input Bar (abort).
- **C-y**: Paste text from clipboard into the Input Bar (yank-selection).
- **TAB**: Clockwise tab complete the current string, if possible. Press TAB again to cycle through completions.
- **S-TAB**: Counter-clockwise tab complete the current string, if possible. Press S-TAB again to cycle through completions.
4.3 Programming The Message Bar

`echo-string screen msg` [Function]
Display string in the message bar on screen. You almost always want to use `message`.

`message fmt &rest args` [Function]
run FMT and ARGS through ‘format’ and echo the result to the current screen.

`*input-history-ignore-duplicates*` [Variable]
Do not add a command to the input history if it’s already the first in the list.

`copy-last-message` [Command]
Copy the last message displayed into the X selection

4.4 Programming the Input Bar

New input behavior can be added to the input bar by creating editing functions and binding them to keys in the *input-map* using `define-key`, just like other key bindings.

An input function takes 2 arguments: the input structure and the key pressed.

`read-one-line screen prompt &key (initial-input ) require-match` [Function]
Read a line of input through stumpwm and return it. returns nil if the user aborted.

`read-one-char screen` [Function]
Read a single character from the user.

`completing-read screen prompt completions &key (initial-input ) require-match` [Function]
Read a line of input through stumpwm and return it with TAB completion. completions can be a list, an fbound symbol, or a function. if its an fbound symbol or a function then that function is passed the substring to complete on and is expected to return a list of matches. If require-match argument is non-nil then the input must match with an element of the completions.

`input-insert-string input string` [Function]
Insert string into the input at the current position. input must be of type `input-line`. Input functions are passed this structure as their first argument.

`input-insert-char input char` [Function]
Insert char into the input at the current position. input must be of type `input-line`. Input functions are passed this structure as their first argument.

`*input-map*` [Variable]
This is the keymap containing all input editing key bindings.
5 Windows

`next` [Command]
Go to the next window in the window list.

`pull-hidden-next` [Command]
Pull the next hidden window into the current frame.

`prev` [Command]
Go to the previous window in the window list.

`pull-hidden-previous` [Command]
Pull the next hidden window into the current frame.

`delete-window &optional (window (current-window))` [Command]
Delete a window. By default delete the current window. This is a request sent to the window. The window’s client may decide not to grant the request or may not be able to if it is unresponsive.

`kill-window &optional (window (current-window))` [Command]
Tell X to disconnect the client that owns the specified window. Default to the current window. if `delete-window` didn’t work, try this.

`echo-windows &optional (fmt *window-format*) (group (current-group)) (windows (group-windows group))` Display a list of managed windows. The optional argument `fmt` can be used to override the default window formatting.

`other-window &optional (group (current-group))` [Command]
Switch to the window last focused.

`pull-hidden-other` [Command]
Pull the last focused, hidden window into the current frame.

`renumber nt &optional (group (current-group))` [Command]
Change the current window’s number to the specified number. If another window is using the number, then the windows swap numbers. Defaults to current group.

`meta key` [Command]
Send a fake key to the current window. key is a typical StumpWM key, like C-M-o.

`select-window query` [Command]
Switch to the first window that starts with query.

`select-window-by-number num &optional (group (current-group))` [Command]
Find the window with the given number and focus it in its frame.

`title title` [Command]
Override the current window’s title.
windowlist &optional (fmt *window-format*)  
Allow the user to Select a window from the list of windows and focus the selected window. For information of menu bindings See Section 12.1 [Menus], page 39. The optional argument fmt can be specified to override the default window formatting.

fullscreen  
Toggle the fullscreen mode of the current window. Use this for clients with broken (non-NETWM) fullscreen implemenations, such as any program using SDL.

info &optional (fmt *window-info-format*)  
Display information about the current window.

refresh  
Refresh current window without changing its size.

redisplay  
Refresh current window by a pair of resizes, also make it occupy entire frame.

*window-format*  
This variable decides how the window list is formatted. It is a string with the following formatting options:

%\n Substitute the window number.
%\s Substitute the window’s status. * means current window, + means last window, and - means any other window.
%\t Substitute the window’s name.
%\c Substitute the window’s class.
%\i Substitute the window’s resource ID.
%\m Draw a # if the window is marked.

Note, a prefix number can be used to crop the argument to a specified size. For instance, ‘%20t’ crops the window’s title to 20 characters.

*window-name-source*  
This variable controls what is used for the window’s name. The default is :title.

:title Use the window’s title given to it by its owner.
:class Use the window’s resource class.
:resource-name Use the window’s resource name.

*new-window-prefered-frame*  
nil
5.1 Window Marks

Windows can be marked. A marked window has a # beside it in the window list. Some commands operate only on marked windows.

mark
Toggle the current window’s mark.

clear-window-marks &optional (group (current-group)) (windows (group-windows group)) Clear all marks in the current group.
pull-marked
Pull all marked windows into the current frame and clear the marks.

5.2 Customizing Window Appearance

*maxsize-border-width*
The width in pixels given to the borders of windows with maxsize or ratio hints.

*transient-border-width*
The width in pixels given to the borders of transient or pop-up windows.

*normal-border-width*
The width in pixels given to the borders of regular windows.

>window-border-style*
This controls the appearance of the border around windows. valid values are:
:thick All space within the frame not used by the window is dedicated to the border.
:thin Only the border width as controlled by *maxsize-border-width* *normal-border-width* and *transient-border-width* is used as the border. The rest is filled with the unfocus color.
:tight The same as :thin but the border surrounds the window and the wasted space within the frame is not obscured, revealing the background.
:none Like :tight but no border is ever visible.

After changing this variable you may need to call sync-all-frame-windows to see the change.

set-win-bg-color color
Set the background color of the window. The background color will only be visible for windows with size increment hints such as ‘emacs’ and ‘xterm’.

set-focus-color color
Set the border color for focused windows. This is only used when there is more than one frame.

set-unfocus-color color
Set the border color for windows without focus. This is only used when there is more than one frame.
**set-normal-gravity** \textit{gravity} \quad [Function]

Set the default gravity for normal windows. Possible values are: \texttt{center} : \texttt{top} : \texttt{left} : \texttt{right} : \texttt{bottom} : \texttt{top-left} : \texttt{top-right} : \texttt{bottom-left} and \texttt{bottom-right}.

**set-maxsize-gravity** \textit{gravity} \quad [Function]

Set the default gravity for maxsize windows.

**set-transient-gravity** \textit{gravity} \quad [Function]

Set the default gravity for transient/pop-up windows.

**gravity** \textit{gravity} \quad [Command]

Set a window’s gravity within its frame. Gravity controls where the window will appear in a frame if it is smaller than the frame. Possible values are:

- \texttt{center}
- \texttt{top}
- \texttt{right}
- \texttt{bottom}
- \texttt{left}
- \texttt{top-right}
- \texttt{top-left}
- \texttt{bottom-right}
- \texttt{bottom-left}

### 5.3 Controlling Raise And Map Requests

It is sometimes handy to deny a window’s request to be focused. The following variables determine such behavior.

A map request occurs when a new or withdrawn window requests to be mapped for the first time.

A raise request occurs when a client asks the window manager to give an existing window focus.

**deny-map-request** \quad [Variable]

A list of window properties that stumpwm should deny matching windows’ requests to become mapped for the first time.

**deny-raise-request** \quad [Variable]

Exactly the same as \texttt{deny-map-request} but for raise requests.

Note that no denial message is displayed if the window is already visible.

**suppress-deny-messages** \quad [Variable]

For complete focus on the task at hand, set this to \texttt{T} and no raise/map denial messages will be seen.
Some examples follow.

```lisp
;; Deny the firefox window from taking focus when clicked upon.
(push '(:class "gecko") stumpwm:*deny-raise-request*)

;; Deny all map requests
(setf stumpwm:*deny-map-request* t)

;; Deny transient raise requests
(push '(:transient) stumpwm:*deny-map-request*)

;; Deny the all windows in the xterm class from taking focus.
(push '(:class "Xterm") stumpwm:*deny-raise-request*)
```

## 5.4 Programming With Windows

### define-window-slot

Create a new window attribute and corresponding get/set functions.

```lisp
define-window-slot attr

Create a new window attribute and corresponding get/set functions.
```

### window-send-string

Send the string of characters to the current window as if they'd been typed.

```lisp
window-send-string string &optional (window (current-window))

Send the string of characters to the current window as if they'd been typed.
```

### *default-window-name*

The name given to a window that does not supply its own name.

```lisp
*default-window-name*

The name given to a window that does not supply its own name.
```

## 5.5 Rule Based Window Placement

### define-frame-preference

Create a rule that matches windows and automatically places them in a specified group and frame. Each frame rule is a lambda list:

```lisp
define-frame-preference target-group &rest frame-rules

Create a rule that matches windows and automatically places them in a specified group and frame. Each frame rule is a lambda list:
```

- **frame-number**
  - The frame number to send matching windows to

- **raise**
  - When non-nil, raise and focus the window in its frame

- **lock**
  - When this is nil, this rule will only match when the current group matches target-group. When non-nil, this rule matches regardless of the group and the window is sent to target-group. If lock and raise are both non-nil, then stumpwm will jump to the specified group and focus the matched window.

- **create**
  - When non-NIL the group is created and eventually restored when the value of create is a group dump filename in *DATA-DIR*. Defaults to NIL.

- **restore**
  - When non-NIL the group is restored even if it already exists. This arg should be set to the dump filename to use for forced restore. Defaults to NIL

- **class**
  - The window's class must match class.
instance  The window’s instance/resource name must match instance.

type  The window’s type must match type.

role  The window’s role must match role.

title  The window’s title must match title.

clear-window-placement-rules  [Function]
Clear all window placement rules.

remember  lock title  [Command]
Make a generic placement rule for the current window. Might be too specific/not specific enough!

forget  [Command]
Forget the window placement rule that matches the current window.

dump-window-placement-rules  file  [Command]
Dump *window-placement-rules* to FILE.

restore-window-placement-rules  file  [Command]
Restore *window-placement-rules* from FILE.
Chapter 6: Frames

6 Frames

Frames contain windows. All windows exist within a frame.

Those used to ratpoison will notice that this differs from ratpoison’s window pool, where windows and frames are not so tightly connected.

pull-window-by-number n &optional (group (current-group))  [Command]
Pull window N from another frame into the current frame and focus it.

hsplit  [Command]
Split the current frame into 2 side-by-side frames.

tvsplit  [Command]
Split the current frame into 2 frames, one on top of the other.

remove-split &optional (group (current-group)) (frame (tile-group-current-frame group)) Remove the specified frame in the specified group (defaults to current group, current frame). Windows in the frame are migrated to the frame taking up its space.

only  [Command]
Delete all the frames but the current one and grow it to take up the entire head.

curframe  [Command]
Display a window indicating which frame is focused.

fnext  [Command]
Cycle through the frame tree to the next frame.

Sibling  [Command]
Jump to the frame’s sibling. If a frame is split into two frames, these two frames are siblings.

fother  [Command]
Jump to the last frame that had focus.

fselect frame-number  [Command]
Display a number in the corner of each frame and let the user to select a frame by number. If frame-number is specified, just jump to that frame.

resize width height  [Command]
Resize the current frame by width and height pixels

balance-frames  [Command]
Make frames the same height or width in the current frame’s subtree.

fclear  [Command]
Clear the current frame.
move-focus $dir$  
Focus the frame adjacent to the current one in the specified direction. The following are valid directions:
  up
  down
  left
  right

move-window $dir$  
Just like move-focus except that the current is pulled along.

next-in-frame  
Go to the next window in the current frame.

prev-in-frame  
Go to the previous window in the current frame.

other-in-frame  
Go to the last accessed window in the current frame.

echo-frame-windows &optional ($fmt$ *window-format*)  
Display a list of all the windows in the current frame.

exchange-direction $dir$ &optional ($win$ (current-window))  
Exchange the current window (by default) with the top window of the frame in specified direction.
  up
  down
  left
  right

*min-frame-width*  
The minimum width a frame can be. A frame will not shrink below this width. Splitting will not affect frames if the new frame widths are less than this value.

*min-frame-height*  
The minimum height a frame can be. A frame will not shrink below this height. Splitting will not affect frames if the new frame heights are less than this value.

*new-frame-action*  
When a new frame is created, this variable controls what is put in the new frame. Valid values are
  :empty The frame is left empty
  :last-window The last focused window that is not currently visible is placed in the frame. This is the default.
6.1 Interactively Resizing Frames

There is a mode called `iresize` that lets you interactively resize the current frame. To enter the mode use the `iresize` command or type `C-t r`.

The following keybindings apply to the mode:

- `C-p` Up
- `k` Shrink the frame vertically.
- `C-n` Down
- `j` Expand the frame vertically.
- `C-f` Right
- `l` Expand the frame horizontally.
- `C-b` Left
- `h` Shrink the frame horizontally.
- `C-g` ESC Abort the interactive resize. NOTE: This currently doesn’t work.
- RET Select the highlighted option.

`iresize` [Command] Start the interactive resize mode. A new keymap specific to resizing the current frame is loaded. Hit `C-g`, RET, or ESC to exit.

`abort-iresize` [Command] Exit from the interactive resize mode.

`exit-iresize` [Command] Exit from the interactive resize mode.

`*resize-increment*` [Variable] Number of pixels to increment by when interactively resizing frames.

6.2 Frame Dumping

The configuration of frames and groups can be saved and restored using the following commands.

`dump-desktop-to-file file` [Command] Dumps the frames of all groups of all screens to the named file.

`dump-group-to-file file` [Command] Dumps the frames of the current group of the current screen to the named file.

`dump-screen-to-file file` [Command] Dumps the frames of all groups of the current screen to the named file.
**restore-from-file** `file`  
[Command]  
Restores screen, groups, or frames from named file, depending on file’s contents.

**place-existing-windows**  
[Command]  
Re-arrange existing windows according to placement rules.
7 The Mode Line

The mode line is a bar that runs across either the top or bottom of a head and is used to display information. By default the mode line displays the list of windows, similar to the output C-t w produces.

Alternatively, external panel applications such as the GNOME panel and KDE’s kicker may be used. Simply starting one of these programs is enough to set it as the mode line of the head it would like to be on (if the panel is Xinerama aware) or whichever head is available. In order to avoid problems displaying menus, configure your panel application for positioning at the top or bottom of the head rather than relying on *mode-line-position*.

The mode line can be turned on and off with the mode-line command or the lisp function stumpwm:toggle-mode-line. Each head has its own mode line. For example:

```
;;; turn on/off the mode line for the current head only.
(stumpwm:toggle-mode-line (stumpwm:current-screen)
                          (stumpwm:current-head))
```

The mode line is updated after every StumpWM command.

To display the window list and the current date on the modeline, one might do the following:

```
(setf stumpwm:*screen-mode-line-format*
     (list "%w | "
          ';(:eval (stumpwm:run-shell-command "date" t)))))

(stumpwm:run-shell-command "date" t) runs the command date and returns its output as a string.
```

**mode-line**
A command to toggle the mode line visibility.

**toggle-mode-line** screen head &optional (format (quote *screen-mode-line-format*))
Toggle the state of the mode line for the specified screen

**screen-mode-line-format**
This variable describes what will be displayed on the modeline for each screen. Turn it on with the function TOGGLE-MODE-LINE or the mode-line command.

It is a list where each element may be a string, a symbol, or a list.

For a symbol its value is used.

For a list of the form (:eval FORM) FORM is evaluated and the result is used as a mode line element.

If it is a string the string is printed with the following formatting options:

- %h: List the number of the head the mode-line belongs to
- %w: List all windows in the current group windows using *window-format*
- %W: List all windows on the current head of the current group using *window-format*
- %g: List the groups using *group-format*
The following variables control the color, position, and size of the mode line.

*mode-line-position*  [Variable]
   Specifies where the mode line is displayed. Valid values are :top and :bottom.

*mode-line-border-width* 1
   nil

*mode-line-pad-x*
   nil

*mode-line-pad-y*
   nil

*mode-line-background-color*
   nil

*mode-line-foreground-color*
   nil

*mode-line-border-color*
   nil

*mode-line-timeout*  [Variable]
   The modeline updates after each command, when a new window appears or an existing one disappears, and on a timer. This variable controls how many seconds elapse between each update. If this variable is changed while the modeline is visible, you must toggle the modeline to update timer.
8 Groups

Groups in StumpWM are more commonly known as virtual desktops or workspaces. Why not create a new term for it?

**gnew** name

Create a new group with the specified name. The new group becomes the current group. If name begins with a dot ("."), the group new group will be created in the hidden state. Hidden groups have group numbers less than one and are invisible to from gprev, gnext, and, optionally, groups and vgroups commands.

**gnew-float** name

Create a floating window group with the specified name and switch to it.

**gnewbg** name

Create a new group but do not switch to it.

**gnewbg-float** name

Create a floating window group with the specified name, but do not switch to it.

**gnext**

Cycle to the next group in the group list.

**gprev**

Cycle to the previous group in the group list.

**gnext-with-window**

Cycle to the next group in the group list, taking the current window along.

**gprev-with-window**

Cycle to the previous group in the group list, taking the current window along.

**gother**

Go back to the last group.

**gmerge** from

Merge from into the current group. from is not deleted.

**groups** &optional (fmt *group-format*)

Display the list of groups with their number and name. *group-format* controls the formatting. The optional argument fmt can be used to override the default group formatting.

**vgroups** &optional gfmt wfmt

Like groups but also display the windows in each group. The optional arguments gfmt and wfmt can be used to override the default group formatting and window formatting, respectively.

**gselect** to-group

Select the first group that starts with substring. substring can also be a number, in which case gselect selects the group with that number.
gmove  to-group
    Move the current window to the specified group.

gkill
    Kill the current group. All windows in the current group are migrated to the next group.

grename  name
    Rename the current group.

grouplist  &optional (fmt *group-format*)
    Allow the user to select a group from a list, like windowlist but for groups

8.1 Customizing Groups

*group-formatters*  [Variable]
    An alist of characters and formatter functions. The character can be used as a format character in *group-format*. When the character is encountered in the string, the corresponding function is called with a group as an argument. The functions return value is inserted into the string. If the return value isn’t a string it is converted to one using prin1-to-string.

*group-format*  [Variable]
    The format string that decides what information will show up in the group listing. The following format options are available:

    %n   The group’s number.
    %s   The group’s status. Similar to a window’s status.
    %t   The group’s name.

current-group  &optional (screen (current-screen))  [Function]
    Return the current group for the current screen, unless otherwise specified.
Chapter 9: Screens

9 Screens

StumpWM handles multiple screens.

**snext**
Go to the next screen.

**sprev**
Go to the previous screen.

**sother**
Go to the last screen.

9.1 Xinerama

StumpWM will attempt to detect Xinerama heads at startup (and at no other time.) Heads are logically contained by screens. In a dual-monitor Xinerama configuration, there will be one screen with two heads. Non-rectangular layouts are supported (frames will not be created in the 'dead zone'.) And message windows will be displayed on the current head—that is, the head to which the currently focused frame belongs.

9.2 Programming With Screens

**current-screen**
Return the current screen.

**screen-current-window** *screen*
Return the current window on the specified screen

**current-window**
Return the current window on the current screen

**screen-list**
The list of screens managed by stumpwm.
10 Interacting With Unix

**run-shell-command**  *cmd &optional collect-output-p*  
[Command]  
Run the specified shell command. If *collect-output-p* is T then run the command synchronously and collect the output. Be careful. If the shell command doesn’t return, it will hang StumpWM. In such a case, kill the shell command to resume StumpWM.

**programs-in-path**  &optional full-path (path (split-string (getenv PATH) :))  
[Function]  
Return a list of programs in the path. if *full-path* is t then return the full path, otherwise just return the filename. *path* is by default the PATH environment variable but can be specified. It should be a string containing each directory separated by a colon.

**pathname-is-executable-p**  pathname  
[Function]  
Return T if the pathname describes an executable file.

**shell-program**  
[Variable]  
The shell program used by run-shell-command.

**getenv**  var  
[Function]  
Return the value of the environment variable.

**(setf getenv) val var**  
[Function]  
Set the value of the environment variable, *var* to *val*. 

11 Interacting With X11

**set-x-selection** text

Set the X11 selection string to *string*.

**get-x-selection &optional timeout**

Return the x selection no matter what client own it.
12 Miscellaneous Commands

The following is a list of commands that don’t really fit in any other section.

emacs
Start emacs unless it is already running, in which case focus it.

banish &optional where
Warp the mouse the lower right corner of the current head.

ratwarp x y
Warp the mouse to the specified location.

ratrelwarp dx dy
Warp the mouse by the specified amount from its current position.

ratclick &optional (button 1)
Simulate a pointer button event at the current pointer location. Note: this function rarely works.

echo-date
Display the date and time.

eval-line cmd
Evaluate the s-expression and display the result(s).

window-send-string string &optional (window (current-window))
Send the string of characters to the current window as if they’d been typed.

reload
Reload StumpWM using asdf.

loadrc
Reload the ~/.stumpwmrc file.

keyboard-quit
Quit StumpWM.

quit

restart-hard
Restart stumpwm. This is handy if a new stumpwm executable has been made and you wish to replace the existing process with it.
Any run-time customizations will be lost after the restart.

restart-soft
Soft Restart StumpWM. The lisp process isn’t restarted. Instead, control jumps to the very beginning of the stumpwm program. This differs from RESTART, which restarts the unix process.
Since the process isn’t restarted, existing customizations remain after the restart.
getsel
   Echo the X selection.

putsel string
   Stuff the string string into the X selection.

command-mode
   Command mode allows you to type ratpoison commands without needing the C-t
   prefix. Keys not bound in StumpWM will still get sent to the current window. To
   exit command mode, type C-g.

copy-unhandled-error
   When an unhandled error occurs, StumpWM restarts and attempts to continue. Un-
   handled errors should be reported to the mailing list so they can be fixed. Use this
   command to copy the unhandled error and backtrace to the X11 selection so you can
   paste in your email when submitting the bug report.

commands
   List all available commands.

lastmsg
   Display the last message. If the previous command was lastmsg, then continue cycling
   back through the message history.

list-window-properties
   List all the properties of the current window and their values, like xprop.

run-commands &rest commands
   Run each stumpwm command in sequence. This could be used if you’re used to
   ratpoison’s rc file and you just want to run commands or don’t know lisp very well.
   One might put the following in one’s rc file:

   (stumpwm:run-commands
       "escape C-z"
       "exec firefox"
       "split")

defcommand name (&rest args) (&rest interactive-args) &body body
   Create a command function and store its interactive hints in *command-hash*. The
   local variable %interactivep% can be used to check if the command was called in-
   teractively. If it is non-NIL then it was called from a keybinding or from the colon
   command.
   INTERACTIVE-ARGS is a list of the following form: ((TYPE PROMPT) (TYPE
   PROMPT) ...)
   each element in INTERACTIVE-ARGS declares the type and prompt for the com-
   mand’s arguments.
   TYPE can be one of the following:

   :y-or-n   A yes or no question returning T or NIL.
   :variable A lisp variable
:function  A lisp function
:command  A stumpwm command as a string.
:key-seq  A key sequence starting from *TOP-MAP*
:window-number  An existing window number
:number  An integer number
:string  A string
:key  A single key chord
:window-name  An existing window’s name
:group  An existing group
:frame  A frame
:shell  A shell command
:rest  The rest of the input yes to be parsed.
:module  An existing stumpwm module

Note that new argument types can be created with DEFINE-STUMPWM-TYPE. PROMPT can be string. In this case, if the corresponding argument is missing from an interactive call, stumpwm will use prompt for its value using PROMPT. If PROMPT is missing or nil, then the argument is considered an optional interactive argument and is not prompted for when missing.

Alternatively, instead of specifying nil for PROMPT or leaving it out, an element can just be the argument type.

**define-stumpwm-type**  
*type (input prompt) &body body*  
[Macro]  
Create a new type that can be used for command arguments. *type* can be any symbol. When *body* is evaluated *input* is bound to the argument-line. It is passed to argument-pop, argument-pop-rest, etc. *prompt* is the prompt that should be used when prompting the user for the argument.

```
(define-stumpwm-type :symbol (input prompt)
  (or (find-symbol (string-upcase
    (or (argument-pop input)
      ;; Whitespace messes up find-symbol.
      (string-trim " 
      (completing-read (current-screen)

prompt
  ;; find all symbols in the
  ;; stumpwm package.
```
(let (acc)
  (do-symbols (s (find-package "STUMPWM"))
    (push (string-downcase (symbol-name s)) acc)
    acc))
  (throw 'error "Abort.")))
"STUMPWM")
(throw 'error "Symbol not in STUMPWM package")))

(defun symbol (sym) ((:symbol "Pick a symbol: ")
  (message "-a" (with-output-to-string (s)
    (describe sym s))))
This code creates a new type called :symbol which finds the symbol in the stumpwm package. The command symbol uses it and then describes the symbol.

run-or-raise cmd props &optional (all-groups
  *run-or-raise-all-groups*) (all-screens *run-or-raise-all-screens*)
 Run the shell command, cmd, unless an existing window matches props. props is a property list with the following keys:

: class    Match the window’s class.

: instance Match the window’s instance or resource-name.

: role      Match the window’s WM_WINDOW_ROLE.

: title     Match the window’s title.

By default, the global *run-or-raise-all-groups* decides whether to search all groups or the current one for a running instance. all-groups overrides this default. Similarly for *run-or-raise-all-screens* and all-screens.

*run-or-raise-all-groups*
 When this is T the run-or-raise function searches all groups for a running instance. Set it to NIL to search only the current group.

*run-or-raise-all-screens*
 When this is T the run-or-raise function searches all screens for a running instance. Set it to NIL to search only the current screen. If *run-or-raise-all-groups* is NIL this variable has no effect.

restarts-menu err
 Display a menu with the active restarts and let the user pick one. Error is the error being recovered from. If the user aborts the menu, the error is re-signalled.

with-restarts-menu &body body
 Execute BODY. If an error occurs allow the user to pick a restart from a menu of possible restarts. If a restart is not chosen, resignal the error.

*startup-message*
 This is the message StumpWM displays when it starts. Set it to NIL to suppress.
Chapter 12: Miscellaneous Commands

*suppress-abort-messages* [Variable]
Suppress abort message when non-nil.

*default-package* [Variable]
This is the package eval reads and executes in. You might want to set this to :stumpwm if you find yourself using a lot of internal stumpwm symbols. Setting this variable anywhere but in your rc file will have no effect.

defprogram-shortcut name &key (command (string-downcase (string name))) (props (backq-list (quote quote) (backq-list (quote class) (string-capitalize command)))) (map *top-map*) (key (kbd (concat H- (subseq command 0 1)))) (pullp nil) (pull-name (intern1 (concat (string name) -PULL))) (pull-key (kbd (concat H-M- (subseq command 0 1))))
Define a command and key binding to run or raise a program. If pullp is set, also define a command and key binding to run or pull the program.

*initializing* [Variable]
True when starting stumpwm. Use this variable in your rc file to run code that should only be executed once, when stumpwm starts up and loads the rc file.

12.1 Menus
Some commands present the options in a menu. The following are the menu key bindings:
C-p Up k Highlight the previous menu option.
C-n Down j Highlight the next menu option.
C-g ESC RET Abort the menu. Select the highlighted option.

12.2 StumpWM's Data Directory
If you want to store StumpWM data between sessions, the recommended method is to store them in `~/.stumpwm.d/`. StumpWM supplies some functions to make doing this easier.

*data-dir* [Variable]
The directory used by stumpwm to store data between sessions.

data-dir-file name &optional type [Function]
Return a pathname inside stumpwm’s data dir with the specified name and type

with-data-file (s file &rest keys &key (if-exists supersede) &allow-other-keys) &body body [Macro]
Open a file in StumpWM’s data directory. keyword arguments are sent directly to OPEN. Note that IF-EXISTS defaults to :supersede, instead of :error.
12.3 Debugging StumpWM

*debug-level* [Variable]
Set this variable to a number > 0 to turn on debugging. The greater the number the more debugging output.

*debug-stream* [Variable]
This is the stream debugging output is sent to. It defaults to *error-output*. It may be more convenient for you to pipe debugging output directly to a file.

redirect-all-output file [Function]
Elect to redirect all output to the specified file. For instance, if you want everything to go to ~/stumpwm.d/debug-output.txt you would do:

   (redirect-all-output (data-dir-file "debug-output" "txt"))

12.4 Timers
StumpWM has a timer system similar to that of Emacs.

run-with-timer secs repeat function &rest args [Function]
Perform an action after a delay of SECS seconds. Repeat the action every REPEAT seconds, if repeat is non-nil. SECS and REPEAT may be reals. The action is to call FUNCTION with arguments ARGS.

cancel-timer timer [Function]
Remove TIMER from the list of active timers.

timer-p timer [Function]
Return T if TIMER is a timer structure.

12.5 Getting Help

describe-key keys [Command]
Either interactively type the key sequence or supply it as text. This command prints the command bound to the specified key sequence.

describe-variable var [Command]
Print the online help associated with the specified variable.

describe-function fn [Command]
Print the online help associated with the specified function.

where-is cmd [Command]
Print the key sequences bound to the specified command.

modifiers [Command]
List the modifiers stumpwm recognizes and what MOD-X it thinks they’re on.
13 Colors

All text printed by stumpwm is run through a coloring engine before being displayed. All color commands start with a ‘^’ (caret) character and apply to all text after it.

\[^0-9\] A caret followed by a single digit number changes the foreground color to the specified color. A ‘*’ can be used to specify the normal color. See the color listing below.

\[^0-90-9\] A caret followed by two digits sets the foreground and background color. The first digit refers to the foreground color and the second digit to the background color. A ‘*’ can be used in place of either digit to specify the normal color. See the color listing below.

\[^B\] Turn on bright colors.
\[^b\] Turn off bright colors.
\[^n\] Use the normal background and foreground color.
\[^R\] Reverse the foreground and background colors.
\[^r\] Turn off reverse colors.
\[^\[\] Push the current colors onto the color stack. The current colors remain unchanged.
\[^]\] Pop the colors off the color stack.
\[^\] Print a regular caret.

The default colors are made to resemble the 16 VGA colors and are:

0 black
1 red
2 green
3 yellow
4 blue
5 magenta
6 cyan
7 white

There are only 8 colors by default but 10 available digits. The last two digits are left up to the user. Section 13.1 [Behind The Scenes Look At Colors], page 42 for information on customizing colors.
13.1 Behind The Scenes Look At Colors

Color indexes are stored in *colors* as a list. The default list of colors leave 2 slots for the user to choose. If you’d like to use ‘Papaya Whip’ and ‘Dark Golden Rod 3’ you might eval the following:

```lisp
(setf *colors* (append *colors* 
    (list "PapayaWhip" 
    "DarkGoldenRod3")))

(update-color-map (current-screen))
```

Of course, you can change all the colors if you like.

**parse-color-string string**  
parse a color coded string into a list of strings and color codes

**uncolorify string**  
Remove any color markup in STRING

***colors***  
Eight colors by default. You can redefine these to whatever you like and then call (update-color-map).

**update-color-map screen**  
Read *colors* and cache their pixel colors for use when rendering colored text.
14 Hooks

StumpWM exports a number of hooks you can use to add customizations; like hooks in Emacs, you add to a hook with the `add-hook` function. For example:

\[(\text{stumpwm::add-hook 'stumpwm:*new-window-hook* 'my-new-window-custos})\]

adds your `my-new-window-custos` function to the list of functions called when a new window appears.

```
(add-hook 'stumpwm:*new-window-hook* 'my-new-window-custos)
```

The following hooks are available:

**new-window-hook**

A hook called whenever a window is added to the window list. This includes a genuinely new window as well as bringing a withdrawn window back into the window list.

**destroy-window-hook**

A hook called whenever a window is destroyed or withdrawn.

**focus-window-hook**

A hook called when a window is given focus. It is called with 2 arguments: the current window and the last window (could be nil).

**place-window-hook**

A hook called whenever a window is placed by rule. Arguments are window group and frame

**start-hook**

A hook called when stumpwm starts.

**internal-loop-hook**

A hook called inside stumpwm’s inner loop.

**focus-frame-hook**

A hook called when a frame is given focus. The hook functions are called with 2 arguments: the current frame and the last frame.

**new-frame-hook**

A hook called when a new frame is created. The hook is called with the frame as an argument.
*message-hook*  
A hook called whenever stumpwm displays a message. The hook function is passed any number of arguments. Each argument is a line of text.

*top-level-error-hook*  
Called when a top level error occurs. Note that this hook is run before the error is dealt with according to *top-level-error-action*.

*focus-group-hook*  
A hook called whenever stumpwm switches groups. It is called with 2 arguments: the current group and the last group.

*key-press-hook*  
A hook called whenever a key under *top-map* is pressed. It is called with 3 argument: the key, the (possibly incomplete) key sequence it is a part of, and command value bound to the key.

*root-click-hook*  
A hook called whenever there is a mouse click on the root window. Called with 4 arguments, the screen containing the root window, the button clicked, and the x and y of the pointer.

*mode-line-click-hook*  
Called whenever the mode-line is clicked. It is called with 4 arguments, the mode-line, the button clicked, and the x and y of the pointer.

*urgent-window-hook*  
A hook called whenever a window sets the property indicating that it demands the user’s attention
15 Modules

StumpWM has a growing number of modules not loaded by default. All modules exist in the contrib/ directory of StumpWM’s archive.

load-module name [Command]

Loads the contributed module with the given NAME.
16 Hacking

For those of you who have worked on Free Software projects before, this part should probably be fairly intuitive.

16.1 Hacking: General Advice

1. Pay attention to file names and contents. If you’re making changes to mode-line related code, don’t put it in `core.lisp`. If you’re introducing some completely new featureset, consider putting all of the new code in a new file.

2. Does a command need to be user-visible (“interactive”) or is it just called by other commands?
   - If it’s not going to be user-visible, you can just use the familiar `(defun foo () ...) syntax.
   - If you want the command to be used interactively, you use StumpWM’s `defcommand` syntax, as in the examples below.

   ```lisp
   (defcommand test (foo bar)
     ((:string "How you’re going to prompt for variable foo: ")
      (:number "How you want to prompt for variable bar: "))
   "This command is a test"
   (body...))
   
   (defcommand test2 () ()
    "This is also a test"
    (body...))
   
   (defcommand title (args) (interactive-args)
    "Doc string"
    (body...))
   
   So basically, inside the first set of parentheses after the function name, you specify what (if any) arguments will be passed to the command. The second set of parentheses tells StumpWM how to get those arguments if they’re not explicitly passed to the command. For example,

   ```lisp
   ((:string "What do you want to do: "))
   ```

   will read a string from the input the user provides. The quoted text is the prompt the user will see. Of course, if you were to, say, call the command `test`, as defined above, from another piece of code, it wouldn’t give the prompt as long as you fed it arguments.

3. Note that all commands defined using the `defcommand` syntax are available both to be called with `C-t ;` and from within other lisp programs, as though they had been defun-ned (which, in fact, they have).

4. Any code that depends on external libraries or programs that some users might not have installed should be placed in the `contrib/` directory.

5. Don’t be afraid to submit your patches to the StumpWM mailing list! It may not immediately make it into the official git repository, but individual users might find it
useful and apply it to their own setup, or might be willing to offer suggestions on how to improve the code.

6. Remember: StumpWM is designed to run on both clisp and on SBCL. If you must use code specific to one or the other, at the very least warn people that it only works with one lisp implementation. Better yet, figure out how to do it in the other distribution and write a statement like this:

```lisp
#+clisp
(your-clisp-code)
#+sbcl
(your-sbcl-code)
```

#to wrap the code for each lisp. Of course, the best option is to find a way to use the same code for clisp and SBCL.

### 16.2 Hacking: Using git with StumpWM

For quite a while now, StumpWM has been using the git version control system for development. If you’re one using one of the official releases or still using the now-obsolete CVS version, you can get the bleeding-edge source code from the official git repository with a single command:

```bash
$ git clone git://git.savannah.nongnu.org/stumpwm.git
```

After this, you’ll have a complete git repository, along with the complete revision history since the switch. Feel free to play around; git has some important features that actually make this safe!

Before we get to that stuff, though, you’re going to want to tell git about yourself so that your information is included in your commits and patches. The very minimum you’re going to want to do is:

```bash
$ git config --global user.name "Anne N. O’Nymous"
$ git config --global user.email "anonymous@foo.org"
```

Be sure to check out the manual for `git-config`—there are several options you might want to set, such as enabling colorized output or changing the editor and pager you use when making commits and viewing logs.

For the sake of argument, let’s say you want to make some major changes to both `user.lisp` and `core.lisp`, add a file called `DANGEROUS_EXPERIMENT_DO_NOT_USE_OR_ELSE.lisp`, and remove the manual because you’re too 1337 for such things. However, you don’t want to break your entire StumpWM setup and start over. Thankfully, you don’t have to. Before you get started, issue this command from the stumpwm directory:

```bash
$ git checkout -b experimental
```

You should now find yourself in a new branch, called experimental. To confirm this, type `git branch`: there should be an asterisk next to the branch you’re currently viewing. At any time, you can type `git checkout master` to return to your master branch, and at any time you can have as many branches of the project as you like. If you want to create a new branch based not on the master branch but on your experimental branch, for example, you’d type:

```bash
$ git checkout -b new-experiment experimental
```
This will place you in a newly-created branch called “new-experiment” which should be identical to your experimental branch as of the last commit (more on that soon). If you’re actually typing out the directions, switch back to your old experimental branch like so:

```
$ git checkout experimental
```

Anyway, now that you have a new branch, create that new file with the long name, which I’ll just call `danger.lisp` for brevity. Make whatever changes you want to it, and when you’re done, tell git about your new file.

```
$ git add dangerous.lisp
```

Now, let’s pretend you’re done making changes. Tell git you’re done for now:

```
$ git commit -a
```

This will open up a prompt in your editor of choice for you to describe your changes. Try to keep the first line short, and then add more explanation underneath (for an example, run the command `git log` and take a look at some of the longer commit explanations). Save that file and then do this:

```
$ git checkout master
$ ls
```

Then look for your new file. It’s not there! That’s because you’ve done all of your work in another branch, which git is currently hiding from you so that you can “check out” the branch called “master.” All is as it should be—your master repository is still safe.

```
$ git checkout experimental
```

Now, delete `manual.lisp` and `stumpwm.texi`. That’s right. Wipe them off the face of the Earth, or at least off the hard drive of your computer. When you’re done, you don’t have to tell git you’ve deleted them; it’ll figure it out on its own (though things may not compile properly unless you edit `Makefile.in` and `stumpwm.asd`). Anyway, go ahead and edit `core.lisp` and `user.lisp`. Really break ’em. Run free! When you’re done, do another commit, as above, and give it a stupid title like “lolz i b0rked stUmpwn guys wTF?!?!?!111!” Now try to compile. Just try. It won’t work. If it does, you’re some kind of savant or something. Keep up the good work. If you’ve actually managed to break StumpWM like you were supposed to, never fear! You have two options at this point.

One is to go back to the master branch (with another git checkout) and just delete your experimental branch, like so:

```
$ git branch -D
```

The “-D” means to force a delete, even if the changes you’ve made aren’t available elsewhere. A “-d” means to delete the branch if and only if you’ve merged the changes in elsewhere.

The other option is to create patches for each of your commits so far, delete the branch, and then apply any working/wanted patches in a new branch. Create your patches (after committing) like so:

```
$ git format-patch -o patches origin
```

(Before doing that you can review your changes with `git log origin`.)

You can also use the `format-patch` command to create a patch of working code to send in to the mailing list.

A developer might ask you to try out something they’re working on. To fetch their master branch, you’d do this:
$ git remote add -f -m master -t master foo git://bar.org/~foo/stumpwm

Here, “foo” is the shorthand name you’ll use to refer to that repository in the future. To checkout a local copy of that repository, you’d then do

$ git checkout --track -b foo-master foo/master

Later you could use git pull foo to update while looking at that branch (and note that git pull with no arguments, in the master branch, will update your StumpWM from the official repository).

Finally, if you want to move your experimental changes into your master branch, you’d checkout your master branch and run:

$ git merge experimental

If there are file conflicts, git diff will show you where they are; you have to fix them by hand. When you’re done, do another

$ git commit -a

to finalize the changes to your master branch. You can then delete your experimental branch. Alternately, you can wait until your changes (assuming you sent them in) make it into the official repository before deleting your experimental branch.

### 16.3 Sending Patches

When sending patches to the mailing list for inclusion in StumpWM, there are a few guidelines that will make everything go smoother.

- Make sure it applies clean to the main git repository
- Ensure that you aren’t introducing tabs, extra blank lines, or whitespace at the end of lines.
- Ensure your patch doesn’t contain irrelevant indenting or reformatting changes.
- Try to make your patch address a single issue. If your patch changes two unrelated issues, break them into two separate patches that can stand on their own.
- Don’t send intermediate patches. When you’re working on a feature you might make several commits to your local repository as you refine it and work out the bugs. When it’s polished and ready to ship, send it as one patch! Sometimes it makes sense to send it as multiple patches if each patch contains a discrete feature or bug fix that can stand on its own. If one of your patches changes code that was added or modified in an earlier patch, consider merging them together and sending them as one.
